Submission to Quantitative Finance: Hard to Beat: Historical Rules versus Conditional Quantile Models for Peak Net-Position Limits

Dear Editors,

Matched FX gains depend on the reference; longer validation narrows weekly regression losses, but a benchmark-default protocol leaves adverse cases; illustrative costs depend on reserve and breach charges.

The manuscript offers matched empirical forecast comparisons for peak inventory limits and separates average accuracy, breaches and illustrative cost preferences. This fits the journal's scope of "both theoretical and empirical approaches" and its coverage of financial econometrics, liquidity modelling, market prediction and operational risk. The scope is stated on the journal's official journal page.

We disclose that the study has circulated as a GitHub working paper, with versioned code and public aggregate results in the study repository. This public version is a preprint rather than a journal publication. The evidence is retrospective and restricted raw inputs are excluded; the source-specific acquisition and reproduction requirements are documented. Author information, funding and competing-interest statements await the authors' confirmation.

Sincerely,

[TO BE COMPLETED BY AUTHOR]
