Dear Editors,

Long-history FX quantile regression lowers matched peak-position forecast loss by 14.8% and 16.6% across two periods, while historical rules prevail in most weekly comparisons.

Please consider "Hard to Beat: Historical Rules versus Conditional Quantile Models for Peak Net-Position Limits" for Journal of Forecasting. The manuscript fits Journal of Forecasting through comparative forecast evaluation, demanding historical benchmarks and practical validation of peak-position limits. Its peak target requires completed forward labels and matched histories and update schedules.

The three empirical findings concern reference stability, weekly benchmark strength and score-breach disagreement. A calibration adjustment retains the later 15.0% FX gain with 329 versus 328 breaches, but rankings against a shorter rolling reference vary by period. Expanded regression loses 34 of 48 weekly panel comparisons; conservative validation leaves large losses. Before calibration, the matched FX score gain accompanies 376 versus 360 breaches. Standard forecasters and elementary target properties support these empirical comparisons.

The submission includes the manuscript, Online Supplement, title-page template and code/results. The calibrated simulation preserves every adverse and numerically failed cell.
