Submission: Hard to Beat: Historical Rules versus Conditional Quantile Models for Peak Net-Position Limits

Dear Editors,

Matched FX gains depend on the reference; longer validation narrows weekly regression losses, but a benchmark-default protocol leaves adverse cases; illustrative costs depend on reserve and breach charges.

The paper fits the *Journal of Forecasting* through matched forecast comparisons, practical validation rules and decision-sensitive evaluation. FX regression lowers matched loss by 14.8% and 16.6%, while its ranking against a shorter rolling reference changes. The original-period learning curve is nonmonotone. Longer validation lowers median losses in both weekly reporting systems; the short-horizon New York Fed comparison also changes the validation endpoint. The benchmark-default protocol has zero weekly median excess, but eight of sixty cases lose by over ten percent and the worst reaches 80.98%. In CFTC, higher reserve charges and lower fixed breach charges generally favor expanded regression, with local exceptions. These illustrative costs do not identify observed economic gains.

The tail-level solver change failed its consistency gate, leaving the original unavailable comparisons and indeterminate judgments unchanged. Editable sources, adverse outcomes, designs and versioned code and public aggregate results accompany the paper. The reproduction instructions disclose raw-input requirements and the corrected clean-clone checks. The evidence is retrospective, and the original FX evaluation period was inspected beforehand. Restricted raw observations and prediction vectors remain excluded; author details and declarations await completion in the supplied templates.

Sincerely,

[TO BE COMPLETED BY AUTHOR]
