Submission: Hard to Beat: Historical Rules versus Conditional Quantile Models for Peak Net-Position Limits

Dear Editors,

Matched FX gains remain reference-dependent, weekly historical controls remain competitive, and expanded-menu regression generally has lower illustrative costs in the CFTC comparisons under higher reserve and lower fixed breach charges, with local exceptions.

The paper fits the *Journal of Forecasting* because it compares complete forecast procedures under matched histories and update schedules. The original-period FX learning curve shows that full regression gains at intermediate history lengths and gives back part of the gain at the longest history. Finite-penalty hindsight still favors history in most short weekly comparisons, while longer validation improves selection toward historical reports. Expanded simulation menus remove large short-history losses, with no further observed median loss from parameter switching in that comparison. Model confidence sets and limit-cost regions connect forecast evaluation to limit validation across related aggregate series. The methods are established, and the evidence remains retrospective. The accompanying materials provide editable manuscript sources, complete records of adverse and unavailable outcomes, official CFTC source records and versioned code and public aggregate results. Restricted FX observations and private prediction vectors remain excluded; author details and declarations await completion in the supplied templates.

Sincerely,

[TO BE COMPLETED BY AUTHOR]
